Objective: Many tumors are poorly immunogenic and resistant to cytotoxic T-lymphocyte–mediated cell lysis. Because cisplatin has been demonstrated to increase tumor cell Fas receptor expression, we hypothesized that cisplatin will enhance cytotoxic T-lymphocyte tumor cell killing and augment the antitumor effect of an active immunotherapy strategy in a poorly immunogenic murine lung cancer model.

Methods: Lewis lung carcinoma cells were exposed to cisplatin in vitro, and Fas receptor expression and apoptosis in response to an agonistic anti-Fas antibody were quantified using flow cytometry. Wild-type and Fas ligand–deficient mice bearing Lewis lung carcinoma flank tumors were then treated with intraperitoneal cisplatin as well as an intratumoral injection of an adenovirus gene transfer vector encoding CD40 ligand. End points included tumor size, animal survival, and Fas expression (determined using immunofluorescence). Cytotoxicity assays were performed using splenocytes from adenovirus gene transfer vector encoding CD40 ligand–treated animals as effectors and cisplatin-treated Lewis lung carcinoma cells as targets.

Results: Cisplatin induced heightened expression of Fas receptor on Lewis lung carcinoma cells in vitro and in vivo and enhanced apoptosis in cells exposed to an agonistic anti-Fas antibody. In vivo, the combination of 1 dose of intraperitoneal cisplatin and intratumoral adenovirus gene transfer vector encoding CD40 ligand inhibited tumor growth and prolonged survival compared with adenovirus gene transfer vector encoding CD40 ligand alone, resulting in a higher cure rate. This effect was lost in Fas ligand–deficient mice. Splenocytes from adenovirus gene transfer vector encoding CD40 ligand–treated wild-type mice lysed cisplatin-treated Lewis lung carcinoma cells more efficiently than untreated Lewis lung carcinoma cells, an effect lost in splenocytes from Fas ligand–deficient mice.

Conclusion: Cisplatin augments the antitumor effect of a cytotoxic T-lymphocyte–mediated immunotherapy strategy, resulting in a higher cure rate than seen with immunotherapy alone. This effect is associated with the enhanced ability of cytotoxic T lymphocytes to lyse tumor cells that have been exposed to cisplatin through Fas/Fas ligand interactions.

Lung cancer is the leading cause of cancer mortality in men and women in the United States. Despite the use of “conventional” antineoplastic therapies (chemotherapy, radiation therapy, and surgical resection), fewer than 15% of patients diagnosed with lung cancer will be cured of their disease. As most patients die of widely metastatic disease, there is clearly a need for novel systemic therapies. Active immunotherapy represents a systemic treatment strategy that may be
potentially useful in many types of malignant disease, including lung cancer. By a variety of mechanisms, these strategies generally focus on enhancing the generation of cytotoxic T lymphocytes (CTLs), which circulate throughout the body and specifically induce tumor cell lysis.2-4

Our laboratory has focused on the development of novel active immunotherapy strategies utilizing in vivo adenovirus (Ad)-mediated gene transfer to induce CTL responses. In this context, a representative approach has been the direct transduction of established tumors with an Ad vector encoding the CD40 ligand cDNA (AdCD40L), which results in tumor-specific CTL generation, regression of established tumors, and long-term protection against tumor rechallenge.5 Although the antitumor effects of AdCD40L are demonstrable in multiple murine tumor models, they are less pronounced in the poorly immunogenic Lewis lung carcinoma (LLC) model, resulting in a negligible long-term cure rate.5

Cisplatin is a platinum-based, chemotherapeutic agent that has formed the backbone of systemic therapeutic regimens for both small cell and non–small cell lung cancer over the last 2 decades.6-8 In addition to its cytotoxic effects, cisplatin has been shown to enhance expression of the cell death receptor, Fas, in multiple human tumor cell lines in vitro, including lung cancer.9-12 Finally, many human lung cancers are poorly immunogenic and do not express significant levels of Fas.13-15 Given this information, as well as the limited antitumor effect of AdCD40L in the poorly immunogenic LLC model, we hypothesized that cisplatin may enhance the antitumor immunity evoked by AdCD40L in this model and that this enhancement would be due to heightened ability of tumor-specific CTLs to induce killing of LLC. In this regard, the data demonstrate: (1) exposure of LLC cells to cisplatin increases Fas expression in vitro and the up-regulated Fas serves as a functional cell death receptor; (2) 1 dose of intraperitoneal cisplatin induces intense Fas expression by established LLC tumors in syngeneic mice, an effect that lasts for at least 3 days; (3) the addition of 1 dose of intraperitoneal cisplatin to cisplatin increases Fas expression on LLC cells treated mice lyse cisplatin-exposed LLC cells more efficiently than naïve LLC cells; and (5) these enhanced antitumor effects of cisplatin are completely abrogated in Fas ligand–/– phenotype was confirmed by flow cytometric analysis of splenocytes (not shown). All animal procedures were approved by the Institutional Animal Care and Use Committee.

Cell Culture

Lewis lung carcinoma (H-2d; a murine lung carcinoma) and B16.F10 (H-2d; a murine melanoma) are both syngeneic to C57BL/6 (H-2b) mice. The cell lines were obtained from American Type Culture Collection (ATCC; Manassas, Va) and maintained in complete Dulbecco’s modified Eagle’s medium (DMEM; 10% fetal bovine serum, 100 μg/mL streptomycin, and 100 U/mL penicillin) at 5% CO2 and 37°C.

Adenovirus Vectors

All gene transfer vectors used in this study are replication-deficient, E1-, E3- vectors based on the adenovirus serotype 5 (Ad5) genome. AdCD40L contains an expression cassette with the murine CD40L cDNA driven by the cytomegalovirus (CMV) early-immediate promoter/enhancer.5 AdNull, a control vector, is similar but contains no transgene. Ad vectors were propagated in human embryonic kidney cells (293 cells; ATCC) and purified through 2 cesium chloride gradient ultracentrifugations as previously described.17 The viral particle concentration was determined by ultraviolet absorbance at 260 nm.18

Quantification of Fas Receptor Expression and Fas-mediated Apoptosis in Vitro

To demonstrate the ability of cisplatin to up-regulate Fas receptor expression in LLC cells in vitro, confluent LLC cells were exposed to either 2.5 μg/mL or 5.0 μg/mL of cisplatin (Sigma Chemical Co, St Louis, Mo) for 3 hours in complete DMEM at 37°C. The cells were washed 3 times with phosphate-buffered saline (PBS) and cultured in complete DMEM for an additional 36 hours. Sham-treated LLC cells served as controls. The cells were then stained with a phycoerythrin (PE)-conjugated rat anti-murine Fas monoclonal antibody (mAb; Pharmingen, San Diego, Calif) or the appropriate isotype-matched, PE-conjugated control mAb (Pharmingen) and subjected to flow cytometric analysis (FACSCalibur; Becton Dickinson, San Jose, Calif).

To assess the functional activity of the up-regulated Fas receptor, LLC cells were cultured in complete DMEM containing 5 μg/mL of cisplatin for 3 hours. The cells were then washed 3 times with PBS and cultured in complete DMEM at 37°C. After 24 hours, 1 μg/mL of an agonistic rat anti-mouse Fas mAb (Jo2; Pharmingen) was added to the media and incubated for an additional 24 hours at 37°C. The cells were washed 3 times with PBS and stained with fluorescein isothiocyanate (FITC)-conjugated annexin V (R&D Systems, Minneapolis, Minn) and TO-PRO-3 iodide ( Molecular Probes, Eugene, Ore) for 15 minutes at 23°C. The cells were then subjected to flow cytometric analysis (FACSCalibur).

Immunofluorescence

To assess the ability of cisplatin to enhance Fas expression on established tumors in vivo, 5 × 106 LLC cells were injected subcutaneously in the right flanks of wild-type C57BL/6 mice. When the tumors were approximately 45 to 50 mm2 in size (day 8), 7 mg/kg of cisplatin was administered as a single intraperitoneal dose. The animals were sacrificed and the tumors harvested 24 and

Materials and Methods

Mice

Six- to eight-week-old female wild-type C57BL/6 (H-2b) and Fas ligand–deficient C57BL/6 (B6Smm.C3-Tnfsf6(−/−)) mice were obtained from Jackson Laboratories (Bar Harbor, Me). The mice were housed under specific pathogen-free conditions and treated according to the National Institutes of Health guidelines. The Fas ligand –/– phenotype was confirmed by flow cytometric analysis of splenocytes (not shown). All animal procedures were approved by the Institutional Animal Care and Use Committee.

The Journal of Thoracic and Cardiovascular Surgery • November 2003
72 hours after cisplatin injection. Sham-treated tumor-bearing mice served as controls. Tumors were snap-frozen in liquid nitrogen, cut into 10-μm sections, and fixed in cold acetone. After blocking nonspecific staining with normal goat serum, the samples were treated with rabbit anti-mouse Fas receptor mAb (Santa Cruz Biotech, Santa Cruz, Calif) in 5% goat serum for 2 hours. The samples were then incubated with an FITC-labeled goat anti-rabbit IgG (Santa Cruz Biotech) for 1 hour in 5% normal goat serum, followed by 5 minutes in 4',6-diamidino-2-phenylindole (1 μg/mL; Molecular Probes) in 0.1% Triton X-100 to stain nuclei (to verify the presence of intact cells on the slides). The sections were then assessed using fluorescence microscopy.

### Ability of Tumor-specific CTLs to Lyse LLC Cells

To demonstrate the effect of cisplatin on the ability of AdCD40L-induced CTLs to lyse LLC cells, LLC tumors were initiated in the flanks of wild-type C57BL/6 mice as described above. When the tumors reached approximately 45 to 50 mm² in size (day 8), AdCD40L or AdNull was administered intratumorally in 100 μL PBS (5 × 10⁰⁰ particles). Untreated animals served as further controls. Ten days after vector administration, spleens were harvested and minced and the red blood cells lysed using ACK buffer (Biosource International, Camarillo, Calif). Splenocytes from 3 animals in each group were pooled, and 8 × 10⁷ splenocytes were restimulated with 2 × 10⁶ mitomycin C–treated LLC cells (100 μg/mL mitomycin C for 90 minutes; Sigma) for 5 days (4 mL of complete RPMI-1640). After restimulation, viable effector cells (splenocytes) at varying effector-to-target ratios (6:1, 20:1, 100:1) were analyzed in a standard 51Cr-release assay for their ability to lyse 51Cr-labeled target cells during a 6-hour incubation at 37°C. Target cells included untreated LLC cells, cisplatin-treated LLC cells, and untreated syngeneic control B16.F10 cells (2 × 10⁷/200 μL/well). The percentage of specific 51Cr-release was calculated as ([experimental release − spontaneous release]/[maximal release − spontaneous release]) × 100. To establish the role of Fas/Fas ligand interactions on the target cell killing ability of AdCD40L-induced CTLs, the same experiment was conducted using splenocytes obtained from tumor-bearing, Fas ligand–deficient mice (B6Smm.CH3-Tnfsf6sd) after vector treatment.  

### Evaluation of the Effect of Cisplatin Administration on the Antitumor Properties of AdCD40L in Vivo

LLC flank tumors were initiated as described above in wild-type C57BL/6 mice. When the tumors reached approximately 45 to 50 mm² in size (day 8), AdCD40L or AdNull was administered intratumorally in 100 μL PBS (5 × 10⁰⁰ particles). Cisplatin (7 mg/kg) was administered as a single intraperitoneal dose concomitantly with vector injection. The size of the flank tumor was assessed in situ every 2 to 3 days by measuring the largest perpendicular diameters using microcalipers and recorded as an average tumor area (mm²). When the animals appeared moribund and the animals in each group were pooled, and 8 × 10⁷ splenocytes were restimulated with 2 × 10⁶ mitomycin C–treated LLC cells (100 μg/mL mitomycin C for 90 minutes; Sigma) for 5 days (4 mL of complete RPMI-1640). After restimulation, viable effector cells (splenocytes) at varying effector-to-target ratios (6:1, 20:1, 100:1) were analyzed in a standard 51Cr-release assay for their ability to lyse 51Cr-labeled target cells during a 6-hour incubation at 37°C. Target cells included untreated LLC cells, cisplatin-treated LLC cells, and untreated syngeneic control B16.F10 cells (2 × 10⁷/200 μL/well). The percentage of specific 51Cr-release was calculated as ([experimental release − spontaneous release]/[maximal release − spontaneous release]) × 100. To establish the role of Fas/Fas ligand interactions on the target cell killing ability of AdCD40L-induced CTLs, the same experiment was conducted using splenocytes obtained from tumor-bearing, Fas ligand–deficient mice (B6Smm.CH3-Tnfsf6sd) after vector treatment.  

### Statistical Analysis

All data are reported as mean ± standard error. Statistical significance between the means was determined using the unpaired, 2-tailed Student’s t test. Survival evaluation was performed using the Kaplan-Meier analysis (P value determined by log-rank test).

### Results

**Exposure of Lewis Lung Carcinoma to Cisplatin Increases Expression of Fas Receptor in Vitro and in Vivo**

The effect of cisplatin on the surface expression of Fas receptor was evaluated by exposing LLC cells to 2 different doses of cisplatin for 3 hours in culture and evaluating the cells using flow cytometry. LLC cells exposed to 2 μg/mL of cisplatin displayed heightened expression of Fas receptor compared with cisplatin-treated cells stained with an isotype-matched control mAb (not shown) or untreated cells (Figure 1, A). When the dose of cisplatin was increased to 5 μg/mL, only a minimal increase was demonstrated over the lower dose (Figure 1, B). To determine if this up-regulation could be demonstrated in vivo, LLC tumors were initiated in the flanks of syngeneic, wild-type mice and 1 intraperitoneal dose of cisplatin (7 mg/kg) was administered after the tumors were established. Tumors were harvested 24 and 72 hours after cisplatin dosing and evaluated for Fas expression using immunofluorescence. Although sham-treated tumors expressed negligible Fas receptor (Figure 2, A and B), tumors from animals treated with cisplatin uniformly expressed Fas 24 hours after dosing (Figure 2, C and D), an effect that was preserved for at least 72 hours (Figure 2, E and F). No expression was detected in any tumors stained with the isotype-matched control Ab (not shown).  

**Up-regulated Fas on LLC Cells Is a Functional Receptor for Apoptosis**

Because cisplatin enhances Fas expression both in vitro and in vivo, experiments were conducted to determine if this up-regulated receptor would initiate apoptosis of the LLC cells upon ligation. LLC cells were exposed to 5 μg/mL cisplatin in vitro for 3 hours; 24 hours later, apoptosis was assessed using annexin staining and flow cytometry. Although sham-treated LLC cells in culture contained some dead cells (Figure 3, A, upper 2 quadrants), cells undergoing apoptosis were not detected (lower, right quadrant). Exposure of LLC cells to the agonistic anti-Fas mAb (Jo2) had no effect on apoptosis (Figure 3, B). Cisplatin exposure alone enhanced apoptosis in LLC cells (Figure 3, C), but this effect was markedly potentiated by the addition of the agonistic anti-Fas mAb (Figure 3, D).

**CTLs from AdCD40L-treated, Tumor-bearing Mice Lyse Cisplatin-treated LLC Cells More Efficiently Than Untreated LLC Cells**

To determine whether the tumor-specific CTLs induced by AdCD40L will lyse LLC cells more efficiently if they have...
been exposed to cisplatin, splenocytes from wild-type mice receiving an intratumoral injection of AdCD40L were isolated, restimulated in vitro, and evaluated in standard cytotoxicity assays. During a 6-hour incubation, splenocytes from AdCD40L-treated mice lysed LLC cells more effectively than untreated LLC cells (Figure 4, A and B). However, these splenocytes were unable to lyse the syngeneic, control cell line, B16.F10 (Figure 4, C). Similarly, there was no lysis noted when splenocytes from either AdNull-treated or untreated tumor-bearing mice were incubated with any target cell (Figure 4, A, B, and C).

To evaluate the role of Fas/Fas ligand interactions in the ability of these tumor-specific CTLs to lyse target cells, the same experiment was repeated in Fas ligand–deficient mice. Splenocytes from these mice were unable to lyse either LLC cells or B16.F10 cells, regardless of cisplatin treatment (Figure 4, D, E, and F).

**Addition of Cisplatin to a CTL-inducing Immunotherapy Strategy in Vivo Enhances Tumor Regression and Prolongs Survival**

To evaluate whether the addition of cisplatin enhances the antitumor effect of AdCD40L in vivo, LLC tumor-bearing wild-type C57BL/6 mice were given intratumoral AdCD40L as well as intraperitoneal cisplatin (1 dose of each), and tumor size was assessed over time. Tumor regression was more pronounced in the animals that received cisplatin plus AdCD40L (Figure 5, A) compared with those in the mice receiving AdCD40L alone (P = .04), AdNull alone (P = .002), cisplatin alone (P = .00009), AdNull plus cisplatin (P = .00002), or no therapy (P = .000003). To establish the role of Fas/Fas ligand interactions in this antitumor effect, the same experiment was repeated in Fas ligand–deficient mice. Strikingly, the ability of cisplatin to enhance the antitumor effect of AdCD40L was abrogated in these transgenic mice (Figure 5, B; P = .2; AdCD40L plus cisplatin versus AdCD40L alone).

Because intratumoral AdCD40L alone results in a minimal cure rate when administered to established LLC tumors in syngeneic mice, animals were followed with survival as the end point. In wild-type C57BL/6 mice, significantly more animals receiving the combination of AdCD40L and cisplatin were cured of their tumors than those receiving the vector alone (Figure 6, A; 43% versus 14%; P = .03). In contrast, no Fas ligand–deficient animals were cured of their tumors, regardless of treatment (Figure 6, B).

**Discussion**

Although innate antitumor immune responses exist, adaptive, specific tumor immunity is generally thought to be a cellular process, mediated by CD8+ CTLs as the immune effector cells.2-4 Activated CTLs are thought to induce cell death in target tumor cells mainly by the perforin/granzyme pathway, a process that requires direct cellular contact and target cell recognition via major histocompatibility complex class I.3,4,20 However, activated CTLs also express Fas ligand, which may bind to and induce apoptosis in tumor cell targets if the tumor expresses the Fas receptor.3,4,20 Lack of Fas expression by tumors may represent 1 mecha-
nism by which tumors can evade CTL-mediated immune responses. For example, Fas receptor expression is absent or reduced in human lung cancers, affecting the susceptibility of these tumors to Fas-mediated apoptosis.\textsuperscript{14}

Given the activity of cisplatin-based chemotherapeutic regimens in small cell and non–small cell lung cancer and the observation that cisplatin increases Fas receptor expression on multiple tumor cell lines in vitro, the present study was designed to determine whether cisplatin will enhance the antitumor effect of a CTL-inducing immunotherapy strategy based on its ability to up-regulate Fas expression on tumors. The data show that cisplatin markedly increases Fas expression in a poorly immunogenic, syngeneic murine lung cancer in vitro and in vivo and that this up-regulated Fas is a functional apoptosis receptor. In addition, tumor-specific CTLs are able to lyse cisplatin-treated LLC cells.

Figure 2. Intraperitoneal administration of cisplatin increases expression of Fas receptor in established LLC flank tumors. Tumors were initiated in syngeneic, wild-type mice and cisplatin was administered as a single intraperitoneal dose 8 days later; 24 and 72 hours after cisplatin treatment (7 mg/kg), the tumors were harvested, snap-frozen, and evaluated using immunofluorescence. Controls consisted of sham-treated mice as well as isotype-matched control mAb used in the staining protocol. Green fluorescence indicates Fas expression. A, Sham treatment. B, Nuclear staining from section in A. C, Twenty-four hours after cisplatin dosing. D, Nuclear staining from section in C. E, Seventy-two hours after cisplatin dosing. F, Nuclear staining from section in E. No green fluorescence was demonstrable in any sections exposed to the isotype-matched control mAb.
more effectively than untreated LLC cells, which translates into more pronounced tumor regression and better cure rate when cisplatin is combined with an active immunotherapy strategy in vivo.

Cisplatin Enhances Tumor Cell Killing by AdCD40L-generated CTLs via Fas/Fas Ligand Interactions

The susceptibility of tumors to active immunotherapy strategies is dependent on both the generation of CTLs and the ability of CTLs, once activated, to induce apoptosis in the tumor cells. LLC is a murine tumor refractory to active immunotherapy compared with other syngeneic murine tumors, exemplified by the consistent lack of long-term cures in mice bearing LLC tumors treated with immunotherapies. As a result, LLC represents an appropriate model in which to evaluate the effect of cisplatin.

The present study suggests that cisplatin augments the ability of tumor-specific CTLs to induce Fas ligand–mediated apoptosis of LLC cells, resulting in more pronounced tumor regression in a flank tumor model. This is supported by several observations. First, LLC cells express little Fas receptor, which is intensely up-regulated by the addition of cisplatin in vitro and in vivo.

Figure 3. The Fas receptor up-regulated by cisplatin is a functional apoptosis receptor. LLC cells were exposed to cisplatin (5 μg/mL) for 3 hours followed by incubation for 24 hours with an agonistic anti-Fas mAb (Jo2; 1 mg/mL). The cells were washed with PBS, stained with FITC-conjugated annexin V as well as TO-PRO-3-iodide, and subjected to 2-color flow cytometry. Shown is a representative experiment of 3 individual studies. Dead cells are depicted in the upper 2 quadrants, and cells undergoing apoptosis are depicted in the lower right quadrant. A, Untreated LLC cells. B, LLC cells exposed to Jo2 mAb alone. C, LLC cells exposed to cisplatin alone. D, LLC cells exposed to cisplatin and Jo2 mAb.
sessed no ability to lyse LLC in any of the groups, implying that the major mechanism of apoptosis induction by CTLs generated via AdCD40L is the Fas/Fas ligand pathway, as opposed to the perforin/granzyme pathway. This finding is consistent with other published data showing CTLs can induce tumor cell apoptosis in the absence of perforin.

Immunohistochemical analysis of human lung cancer has revealed Fas expression in only 30 to 50% of tumors. In addition, lung cancer patients with Fas-expressing tumors have been demonstrated to have significantly longer median survival than patients with Fas-negative tumors, and apoptosis induced by an agonistic anti-Fas antibody has been shown to correlate with the degree of Fas expression in human lung cancer cell lines. Finally, up-regulation of Fas receptor on human tumor cell lines has resulted in accentuated Fas-mediated cytotoxicity by allogeneic peripheral blood lymphocytes. These data, combined with the data in the present study, suggest that up-regulation of Fas receptor by cisplatin may be of benefit when used in conjunction with active immunotherapy in patients with lung cancer.

Clinical Implications of Cisplatin Combined With AdCD40L

Because lung cancer is associated with poor survival, with most patients dying of disseminated disease, active immunotherapy warrants investigation as a novel therapeutic strategy. However, tumor-associated antigens are poorly characterized and heterogeneously expressed in human lung cancers, making antigen-specific vaccination strategies problematic. AdCD40L is a strategy that does not require prior knowledge of specific tumor antigens and, as such, may represent a valid approach for this disease. Because cisplatin is an established drug in the treatment of lung cancer, the finding that it also augments the antitumor effect of a CTL-mediated immunotherapy strategy is highly relevant for clinical application. A potential drawback of this approach is that the ability of chemotherapeutics to enhance Fas receptor expression in some cell lines requires the presence of wild-type p53, although human non–small cell lung cancer is associated with p53 mutations in approximately 50% of cases.

Figure 4. CTLs from tumor-bearing, wild-type C57BL/6 mice are more effective at lysing LLC cells exposed to cisplatin than untreated LLC cells, an effect abrogated in Fas ligand–deficient mice. Ten days following injection of either AdCD40L and AdNull (5 × 10⁹ particles in 100 μL) into established LLC tumors, splenocytes were harvested, restimulated with mitomycin C–treated LLC cells for 5 days in vitro, and evaluated for cytotoxicity against target LLC cells or cisplatin-treated target LLC cells in a standard ⁵¹Cr release assay. B16.F10 cells were used as a control target cell line. Untreated LLC tumor-bearing mice served as further controls. Data points represent the mean ± SEM of 5 wells for each group. Shown is a representative experiment of 3 individual studies, all with similar results. A, Wild-type splenocytes, LLC target cells treated with cisplatin (5 μg/mL). B, Wild-type splenocytes, untreated LLC target cells. C, Wild-type splenocytes, B16.F10 target cells. D, Fas ligand–deficient splenocytes, LLC target cells treated with cisplatin (5 μg/mL). E, Fas ligand–deficient splenocytes, untreated LLC target cells. F, Fas ligand–deficient splenocytes, B16.F10 target cells.
Whether cisplatin will augment the antitumor activity of AdCD40L in tumors with mutated p53 remains to be determined.

We thank N. Mohamed for help in preparing this manuscript.

Figure 5. Cisplatin enhances the regression of established murine lung cancer induced by AdCD40L in wild-type mice, an effect abrogated in Fas ligand–deficient mice. Eight days after LLC flank tumor initiation, mice were randomized to 6 groups: AdCD40L plus cisplatin (n = 7), AdCD40L alone (n = 7), AdNull plus cisplatin (n = 6), AdNull alone (n = 7), cisplatin alone (n = 6), or untreated (n = 6). All vectors were given intratumorally (5 × 10^10 particles in 100 μL), and cisplatin was given as 1 concomitant, intraperitoneal dose (7 mg/kg). The tumor area was assessed in a blinded fashion at 2- to 3-day intervals. Data points represent the mean ± SEM. A, LLC tumors in wild-type C57BL/6 mice. B, LLC tumors in Fas ligand–deficient mice (B6Smn.CH3-Tnfsf6gld). The arrows indicate the time of tumor treatment.

Figure 6. Cisplatin enhances the long-term cure rate of established murine lung cancer induced by AdCD40L in wild-type mice, an effect abrogated in Fas ligand–deficient mice. Eight days after LLC flank tumor initiation, mice were randomized to 6 groups: AdCD40L plus cisplatin (n = 7), AdCD40L alone (n = 7), AdNull plus cisplatin (n = 6), AdNull alone (n = 7), cisplatin alone (n = 6), or untreated (n = 6). All vectors were given intratumorally (5 × 10^10 particles in 100 μL), and cisplatin was given as 1 concomitant, intraperitoneal dose (7 mg/kg). The mice were killed when the largest tumor diameter reached 15 mm or when the mice appeared moribund. A, LLC tumors in C57BL/6 mice.
