725 cases, in 84% of the cases the valvular surface was the predominant location of the tumor. Nonvalvular location is rare, and just 2 cases have been reported to involve the right atrium. This is the first report of a cardiac papillary fibroelastoma originating from pectinate muscles of the right atrial free wall.

**Conclusion**

Right atrial cardiac papillary fibroelastoma is an extremely rare finding. Only 2 cases have been previously reported in the literature. This is the first report of such a tumor attached to the pectinate muscles of the right atrial free wall.

**Accessory mitral valve causing left ventricular outflow tract obstruction and mitral insufficiency**

Hiroshi Tanaka, MD, Kenji Okada, MD, Teruo Yamshita, MD, Keitaro Nakagiri, MD, Masamichi Matsumori, MD, and Yutaka Okita, MD, Kobe, Japan

We report a case of accessory mitral valve that caused both left ventricular outflow tract (LVOT) obstruction and mitral insufficiency. This was treated surgically with excision of the accessory mitral valve, septal myectomy, and mitral annuloplasty. This is a rare case in which the accessory mitral valve caused both LVOT obstruction and mitral insufficiency describing the detail of the pathology.

**Clinical Summary**

A 65-year-old man was referred to us for the diagnosis of moderate aortic insufficiency, moderate mitral insufficiency, and an abnormal structure in the LVOT. The electrocardiogram showed left ventricular hypertrophy and frequent ventricular arrhythmias. Transesophageal echocardiography demonstrated subaortic obstruction of the LVOT (Figure 1) (moderate aortic insufficiency, septal hypertrophy, and moderate mitral insufficiency), which was supposed to be caused by a cleft in the anterior mitral leaflet. The mean pressure gradient across the LVOT was 43 mm Hg.

At surgery, the aortic valve was tricuspid, with a large fenestration of the left coronary cusp–right coronary cusp commissure portion. There was an abnormal structure in the LVOT that looked like mitral leaflet tissue originating from the anterior mitral leaflet. This structure had chordae tendineae–like structures attached to the left ventricular surface of the anterior mitral leaflet and had interconnection to the chordae tendineae. When hooked by its free edge, the structure was opened like a parachute and occluded the LVOT. Simultaneously, the anterior mitral leaflet was retracted into the LVOT. No clefts were found in the anterior mitral leaflet. The structure was excised completely, and septal myectomy was performed. The left atrium was opened, and the mitral valve was seen to be almost normal, with a mild friction lesion of the anterior...
leaflet. No regurgitation was found after a 28-mm annuloplasty ring (Physio-ring; Edwards Lifesciences, Irvine, Calif) was sutured to the annulus. Aortic valve replacement with a bioprosthetic valve (porcine bioprosthesis valve, 23 mm; Edwards Lifesciences) was performed. No pressure gradient across the LVOT and no mitral insufficiency were documented after surgery. According to histologic examination, the specimen was valve tissue. An echocardiogram 3 months after surgery did not demonstrate any residual LVOT obstruction or mitral insufficiency (Figure 2).

Discussion
Accessory mitral valve causing LVOT obstruction was first described by McLean and colleagues1 in 1963. Two thirds of instances of this pathologic entity are associated with other congenital cardiac anomalies, and symptoms thus would develop in the early childhood period. Among adults, most patient who underwent surgery have had a presentation of LVOT obstruction. However, no reports have noted mitral insufficiency associated with isolated accessory mitral valve.4,5 The membrane insertion of the accessory mitral valve is usually attached to aortomitral continuity; with respect to the chordae tendineae–like structure of the accessory mitral valve, however, many variations have been reported, such as the anterior mitral valve chordae (n = 16/32), anterior papillary muscle (n = 14/32), anterior mitral leaflet valve (n = 9/32), left ventricular wall (n = 7/32), accessory papillary muscle (n = 4/32), and interventricular septum (5/32).2,3 In our case, mitral insufficiency had been assumed preoperatively to be caused by a cleft on the lateral portion of the anterior mitral leaflet. The systolic traction of the parachutelike accessory valve leaflet that rendered the anterior mitral leaflet retracted into the LVOT probably yielded the rare phenomenon of LVOT obstruction with mitral insufficiency (Figure 2).

In conclusion, we report a case of accessory mitral valve that caused both LVOT obstruction and mitral insufficiency. Our patient underwent surgery of excision of the accessory mitral valve, septal myectomy, and mitral annuloplasty.
