Objective: Limited exposure and visualization and technical complexity have affected resident training in mitral valve surgery. We propose simulation-based learning to improve skill acquisition in mitral valve surgery.

Methods: After reviewing instructional video recordings of mitral annuloplasty in porcine and plastic models, 11 residents (6 integrated and 5 traditional) performed porcine model mitral annuloplasty. Video-recorded performance was reviewed by attending surgeon providing audio formative feedback superimposed on video recordings; recordings were returned to residents for review. After 3-week practice with plastic model, residents repeated porcine model mitral annuloplasty. Performance assessments initially (prefeedback) and at 3 weeks (postfeedback) were based on review of video recordings on 5-point rating scale (5, good; 3, average; 1, poor) of 11 components. Ratings were averaged for composite score.

Results: Time to completion improved from mean 31 ± 9 minutes to 25 ± 6 minutes after 3-week practice (P = .03). At 3 weeks, improvement in technical components was achieved by all residents, with prefeedback scores varying from 2.4 ± 0.6 for needle angles to 3.0 ± 0.5 for depth of bites and postfeedback scores of 3.1 ± 0.8 for tissue handling to 3.6 ± 0.8 for suture management and tension (P ≤ .001). Interrater reliability was greater than 0.8. In this sample, composite scores of first-year integrated and traditional residents were lower than those of senior level residents; comparatively, third-year integrated residents demonstrated good technical proficiency.

Conclusions: Simulation-based learning with formative feedback results in overall improved performance of simulated mitral annuloplasty. In complex surgical procedures, simulation may provide necessary early graduated training and practice. Importantly, a “passing” grade can be established for proficiency-based advancement. (J Thorac Cardiovasc Surg 2011;141:107-12)

Mitrail valve surgery represents a technically challenging surgical procedure to perform and to teach. For instance, in mitral regurgitation, improved survival is associated with mitral valve repair relative to replacement, 1,2 but choosing the right approach requires not only technical expertise but both extensive knowledge of anatomy and pathophysiology and sound intraoperative judgment. Current Accreditation Council for Graduate Medical Education requirements 3 do not mandate that a specific number of mitral valve procedures be performed by the resident during training; rather, there is a requirement of 50 valve procedures, with no distinction between aortic and mitral valve surgery. Additionally, there may be a limited volume of mitral valve surgery at a given institution, further affecting the training experience.

Simulation-based learning has been proposed as an approach to enhance resident performance in cardiothoracic surgery. 4-10 We propose that resident experience in mitral valve surgery can be augmented by the introduction of such training during residency. By evaluating technical components of mitral valve annuloplasty that define competency and helping residents achieve these standards through simulation, we hope to facilitate skills training and acquisition in mitral valve surgery.

MATERIALS AND METHODS

At a single institution during the transition from a traditional to an integrated cardiothoracic surgical residency training program, 11 residents (5 previously trained in general surgery [traditional program] and 6 in the 6-year integrated program) participated in this study at the beginning of the academic year. Residents in years 1 to 3 of the integrated program (R1–R3) and those in year 1 of the traditional program (T1) had not previously performed mitral valve surgery in the clinical setting. With the exception of a single R3 resident who had performed a single cardiac surgical case, none of the integrated residents (R1–R3) had performed any cardiac surgical case as surgeon rather than assistant. Neither of the T1 residents...
had performed any cardiac surgical cases as surgeon, because they had just completed general surgical residency. Residents in years 2 and 3 of the traditional program (T2 and T3) had performed mitral valve procedures before this simulation exercise. The 2 T2 residents had performed 19 and 20 cases. The T3 resident had performed nearly 240 cases as surgeon. Approval to conduct this study was obtained from the institutional review board.

Porcine Heart Model
Explanted porcine hearts were placed in the container (Wet-Lab, Ltd, Kenilworth, Warwick, UK) and situated to present the left atrium and mitral annular plane at an angle mimicking that in the operating room. The left atrium was opened, and stay sutures were placed to expose the mitral valve and annulus in an anatomically correct configuration, with visibility of the anterior annulus, posterior annulus, and commissures (Figure 1). The depth of the annulus relative to the top of the container was approximately 6 cm. The exposure in this porcine model provides the trainee with an opportunity for assessment of the valve leaflets, annulus, and subvalvular structures.

Plastic Mitral Valve Model
The plastic mitral valve model is a silicone-based cylinder with an opening of 7 cm in diameter and a depth of 5.5 cm (Chamberlain Group, Great Barrington, Mass; Figure 2). The commissure-to-commissure distance is 35 mm, and the anteroposterior dimension measures 26 mm. The model is moderately pliable, which permits some degree of traction and relaxation during suture placement. The cylindrical configuration and the relatively flat plane of the annulus require awareness of needle angles (ie, mounting the needle on the needle driver) for optimal placement of the sutures. The annulus provides reasonable tactile response to suture placement, which permits assessment of the depth of bites, suture advance, and spacing between sutures.

Protocol
All residents reviewed instructional video recordings demonstrating how to perform a mitral annuloplasty with both the porcine model and the plastic mitral model. A few days later, each resident performed a mitral annuloplasty with the porcine model (prefeedback). Standard surgical instruments were used. Sutures were 2-0 Ethibond with RB-1 needles (Ethicon, Inc, Somerville, NJ), and the annuloplasty rings were either Sorin Annuloflow or Sorin Annuloflex (Sorin Group USA, Arvada, Colo). The procedure was timed and video recorded with a head-mounted camera and 2 peripheral cameras. All data were stripped of identifying information and stored on a computer hard drive. Video recordings were submitted to a senior faculty surgeon (J.I.F.) blinded to the identity of the resident. Formative feedback was given as a narrated video recording (audio recording superimposed on the video recording) and returned to each resident for review within 1 week. Residents were given 2 additional weeks to practice the exercise on the plastic mitral model after reviewing the video recording with feedback. Instruments, sutures, and annuloplasty ring were provided. Home practice times were recorded. Three weeks after the initial simulation session, the residents repeated mitral annuloplasty with the porcine model (postfeedback); these procedures were video recorded. Resident performance was evaluated on the basis of review of the video recordings in a blinded fashion by 2 surgeons (J.I.F., T.A.B.) familiar with the use of the rating scale.

Performance Assessment
Resident performance was assessed according to a 5-point rating scale modified from the Objective Structured Assessment of Technical Skills described by Reznick and colleagues11,12 (Table 1). The 11 components of the procedure assessed included identification of anterior annulus, identification of posterior annulus, needle angles, needle removal from annulus, tissue handling, depth of bite, suture advance along annulus, spacing between sutures, situating mitral ring, knot-tying, and suture management and tension. A composite score averaging the scores of the 11 components was calculated for each resident.

Statistical Analysis
Data are presented as mean ± SD. Time to completion data were analyzed with a paired t test that compared prefeedback times with postfeedback times. Components of the rating scale (prefeedback and postfeedback) were analyzed with paired t tests. To assess interrater reliability when scoring the participants, we used the statistic Savr described...
by Gaba and associates. This statistic is a variant of Sav, which is based on the k-like statistics of interrater agreement referenced to chance. Savr takes into account the ordinal nature of the scale and can accommodate 2 or more raters. For Savr, the by chance reference is computed on the assumption that raters would have an equal chance of using any of the rating scale elements in rating any particular item and subject. Correlation between home practice time and time to completion and composite score was obtained with a Pearson coefficient.

RESULTS

Anastomosis Times

Time to completion improved from $31 \pm 9$ minutes at the prefeedback session to $25 \pm 6$ minutes after 3 weeks of practice ($P = .03$; Figure 3). Residents who required longer than 40 minutes at the initial session demonstrated marked improvement, whereas those who completed the initial exercise in less than 25 minutes showed modest to no improvement after practice. Improvement in time to completion was seen both in integrated residents (mean from $33 \pm 9$ minutes to $25 \pm 6$ minutes) and in traditional residents (mean from $29 \pm 11$ minutes to $23 \pm 6$ minutes).

Technical Skills Assessment

Performance assessment demonstrated an improvement in each of the components (Table 2). The technical scores varied from $2.4 \pm 0.6$ for needle angles to $3.0 \pm 0.5$ for depth of bite at the prefeedback session. After 3 weeks (postfeedback), performance improved in all components, with scores varying from $3.1 \pm 0.8$ for tissue handling to $3.6 \pm 0.8$ for suture management and tension. The degree of improvement appeared to be greatest in the identification of anterior annulus, needle angles, and suture management and tension. The lowest scores at the postfeedback session were in tissue handling ($3.1 \pm 0.8$), needle angles ($3.2 \pm 0.5$), and removing the needle from the annulus ($3.2 \pm 0.7$). The interrater reliability for the performance rating scores was greater than 0.8, demonstrating good reliability.

At the prefeedback session, 8 residents demonstrated a composite score less than 3. At the postfeedback session, 3 residents failed to achieve a composite score of at least 3, whereas 5 residents achieved a score of at least 3 in each component along with a composite score of at least 3. There was no correlation between postgraduate year and time to completion improvement or overall score improvement ($-0.3$ and $0.1$, respectively). Performance of the integrated residents improved from a score of $2.6 \pm 0.6$ to $3.3 \pm 0.7$ ($P < .001$), whereas performance of the traditional residents improved from $2.9 \pm 0.7$ to $3.5 \pm 0.6$ ($P < .001$). On average, residents practiced a mean of 3 hours (median, 2 hours; range, 0–10 hours) after reviewing the video feedback; practice time showed no to low correlation with improvement in time to completion or composite score (Pearson coefficients of 0.4 and $-0.3$, respectively). In this small sample, the composite scores of first-year integrated and traditional residents were lower than those of senior level residents; comparatively, the third-year integrated residents demonstrated good technical proficiency (Figure 4).

DISCUSSION

In this study, time to completion and resident performance in mitral annuloplasty were improved by means of simulation and skills training with a period of practice and formative feedback. According to a global rating scale, both integrated and traditional residents showed improvement in the technical skills components, with composite scores of first-year integrated and traditional residents being lower than those of senior level residents; comparatively, third-year integrated residents demonstrated good technical proficiency. By providing the basis to develop an overall score, an important implication is that a “passing” grade...
(eg, 3 out of 5 points) can be established for proficiency-based advancement.

With changes in residency training, the number of cases performed by cardiac surgical trainees has been lower during each year of training after implementation of work-hour restrictions, with an average of 460 total cases performed during the 1999 to 2002 interval compared with 337 cases during the 2003 to 2007 time interval. Also inherent in the transition from a traditional general surgery–based training paradigm to an integrated 6-year cardiothoracic surgical residency is the elimination of complex general surgical cases. Thus simulation-based skills training in this and previous studies has been proposed as an approach to enhance resident performance in cardiothoracic surgery. By focusing on components of surgical technique by using partial-task trainers and practice outside

FIGURE 3. Times to completion before and after feedback for each resident with porcine mitral valve model. Integrated residents are designated by year out of medical school (PGY) as R1, R2, or R3. Traditional residents are designated by year in cardiothoracic surgery residency as T1, T2, or T3.
the operating room, residents can improve their basic technical skills in a graduated fashion and thus maximize their clinical experience.4-6

Mitral valve surgery is a complex procedure, requiring not only technical expertise but both extensive knowledge of anatomy and pathophysiology and sound intraoperative judgment. The focus of this study was directed toward the technical aspect of the annular suture placement and seating the annuloplasty ring. Although this focus is limited in the overall scope of mitral valve surgery, we propose that such technical skills must be mastered before any attempts are made at mitral valve surgery in the clinical setting. By acquiring these basic skills, the resident can focus on the cognitive and procedural components of mitral valve surgery in the operating room, such as attaining adequate exposure, assessing the pathology, and determining the appropriate approach and repair techniques. In this study, integrated residents overall (R1–R3) improved their postfeedback performance to a level that exceeded the scores of first-year traditional residents (T1) at the prefeedback session. This finding can be attributed to earlier exposure to and focus on cardiac surgical procedures in the integrated training program. Although these integrated residents had not previously performed mitral valve surgery in the clinical setting, some had participated in relevant “wet lab” experiences (R2 and R3 more than T1) or in previous research involving large animal surgery; importantly, they had served as a second assistant in many cardiac surgical procedures.

Despite the emphasis on home practice and deliberate practice, what is troubling is that many residents do not fully appreciate the importance of such practice in skill acquisition, as evidenced by a mean practice time of 3 hours during 2 weeks in this study. Because home practice is self-reported, its intensity and thus its impact are difficult
to compare among trainees; nonetheless, it is imperative that the concept of deliberate practice be instilled in all residents, especially in view of work-hour restrictions and changes in residency training, with fewer open surgical cases in general surgery rotations. On the basis of evidence from other domains of expertise and expert performance, it is critically important to have teaching or “coaching” in the simulation laboratory by a skilled surgical educator, so that formative feedback and definition of areas of weakness requiring further practice or remediation can be carried out. This process could be similar to other domains (e.g., music and sports), in which such coaching and feedback may take no more than a few hours a week. For the resident to improve his or her technical skills, defined practice periods at home and in a simulation laboratory are thus critically necessary.

Limitations

Mitral valve and subvalvular structures in the porcine model are not fully representative of the human heart, but the porcine model does provide good tactile feedback and realistic anatomic landmarks. Another limitation is that the silicone-based mitral valve model is of moderate rather than high fidelity. Practice on such a model may account for the fact that there was low to no correlation with improvement on the porcine heart model. As noted, the plastic model does provide some of the components of mitral valve surgery that we consider important; however, development of more realistic and challenging models and simulators is necessary. Simulation-based learning and skills training in cardiac surgery may not transfer to the operative setting with high-stakes, open surgical procedures; transferability will require definition of the tasks that can be simulated and that can be accurately assessed in the operating room without negatively affecting patient safety. The 11 components used in the rating scale were determined to represent surgical skill at a single institution; other components not studied may be deemed equally or more important by others. The composite score may not truly represent the resident’s performance, because each component comprising the overall score is given equal weight; the intent of the composite score was to present an estimate of the overall performance to provide a means for comparison in this study. To use a composite score or grade for summative assessment, it will be necessary to establish consensus among subject matter experts and to weigh each component of the evaluation. It is recognized that the relatively small number of participants limits the extent to which comparisons can be made between integrated and traditionally trained residents. Also, because this cohort of residents was limited to a single institution, a multi-institutional study is necessary to define the role for cardiac surgical simulation in the development of a technical skills curriculum and assessment. Future work will investigate the use of more realistic simulators and a strategy of mandatory practice with feedback (defined length and intensity of practice), which may demonstrate a correlation between degree of practice and improved performance.

This study suggests that introducing simulation exercises in mitral valve surgery provides an effective means of enhancing the resident’s mastery of skills. By developing a standardized method of assessment based on these 11 components, we have established a technique that permits an individualized approach to remediation and practice. On the basis of our comparison of data between integrated and traditional residents, this type of strategy with simulation-based skills learning may offer a solution to the some of the limitations of training residents in the current era.

We gratefully acknowledge David Gaba, MD, for his assistance with the statistical analysis.
