Percutaneous edge-to-edge repair in high-risk and elderly patients with degenerative mitral regurgitation: Midterm outcomes in a single-center experience

Maurizio Taramasso, MD,¹ Francesco Maisano, MD,¹ Paolo Denti, MD,¹ Azeem Latib, MD,³ Giovanni La Canna, MD,³ Antonio Colombo, MD,³ and Ottavio Alfieri, MD²

Objective: The study objective was to report the midterm outcomes of MitraClip implantation in inoperable or high-risk surgical candidates with degenerative mitral regurgitation.

Methods: From October 2008, data of all high-risk or elderly patients with severe degenerative mitral regurgitation who underwent MitraClip implantation were prospectively collected.

Results: Forty-eight high-risk consecutive patients with severe degenerative mitral regurgitation underwent MitraClip implantation (mean age, 78.5 ± 10.8 years; 56.6% of the patients were aged ≥80 years). Mean Society of Thoracic Surgeons score was 12% ± 10%, and 71% were in New York Heart Association class III or IV. Mean left ventricular ejection fraction was 57% ± 11%. The device was successfully implanted in 47 of 48 patients (98%). In-hospital mortality was 2%. The median intensive care unit stay was 22 hours; patients were discharged from the hospital in an average of 4.5 ± 2.4 days. PredischARGE echocardiography showed a mitral regurgitation reduction to grade 2+ or less in 43 of 47 patients (91.5%). Actuarial survival was 89% ± 5.2% and 70.2% ± 9% at 1 and 2 years, respectively (82% ± 9% in patients aged <80 years and 95% ± 4.4% in patients aged ≥80 years at 1 year; P = .9). Freedom from mitral regurgitation 3+ or greater was 80% ± 7% at 1 year and 76.6% ± 7% at 2 years. At 1 year, 93% of survivors were in New York Heart Association class I or II (100% of patients aged <80 years and 88% of patients aged ≥80 years; P = .4). Significant quality of life improvements were documented. A significant improvement in 6-minute walk test performance was observed.

Conclusions: MitraClip therapy is a valuable alternative to surgery in high-risk and elderly patients with degenerative mitral regurgitation. Clinical benefits also are obtained in octogenarians. (J Thorac Cardiovasc Surg 2014;148:2743-50)

See related commentary on pages 2750-1.

Surgical repair represents the optimal treatment for severe degenerative mitral regurgitation (DMR) because of its well-documented advantages over valve replacement in terms of perioperative mortality, preservation of postoperative left ventricular function, and long-term survival.¹,² Indeed, if performed before the onset of limiting symptoms or the development of left ventricular dysfunction, mitral valve (MV) repair is able to restore normal life expectancy and quality of life.³ Currently, more than 90% of degenerative lesions can be repaired successfully in high-volume centers, with low morbidity and fast recovery.⁴ In view of these results, elective MV repair may be indicated even in asymptomatic patients with severe DMR.⁷

However, in real-world clinical practice, a large number of patients with severe mitral regurgitation (MR) are denied surgery: The Euro Heart Survey conducted by the European Society of Cardiology showed that up to 50% of the patients with severe MR currently are denied surgical treatment because they are thought to be at too high risk for surgery because of advanced age or comorbidities.⁸ Moreover, the prevalence of DMR increases in elderly persons,⁹ and advanced age is one of the main risk factors of mortality and major morbidity after cardiac surgery.¹⁰ Therefore, over the past years, new transcatheter techniques have been developed to treat MR with less-invasive approaches. Although less effective in reducing MR compared with surgical repair,¹¹,¹² MitraClip therapy (Abbott Vascular Inc, Menlo Park, Calif) has been shown to improve functional and clinical outcome in inoperable or high-risk patients.¹³-¹⁸ Few data are available today on the midterm clinical outcomes of high-risk patients with DMR after MitraClip implantation.
METHODS

We retrospectively analyzed the clinical and echocardiographic data of a cohort of consecutive patients who underwent MitraClip therapy between October 2008 and July 2013 for severe or moderately severe symptomatic DMR. All patients underwent preoperative coronary angiography and transesophageal Doppler echocardiography. Clinical, Doppler echocardiographic, operative, and outcome data were prospectively collected in a dedicated database. The study protocol was performed in accordance with the institutional ethics committee, and all patients gave written informed consent for the procedures and data collection.

Description of the Procedure

The procedure was performed under general anesthesia in a hybrid operating room, under transesophageal Doppler echocardiography and fluoroscopic guidance. Transseptal puncture was performed using a Brockenbrough needle (Medtronic Inc, Minneapolis, Minn) through peripheral venous access at the right groin. Live real-time 3-dimensional echocardiography was used to improve the conduct of the implantation. A steerable guide catheter was advanced in the left atrium through the transseptal catheter. The delivery system was inserted, and the MitraClip device was implanted in correspondence with the origin of the regurgitation jet, perpendicularly to the coaptation line. If the effect of the implant was satisfactory, the clip was deployed. When necessary, more than 1 clip was implanted. The comprehensive description of the procedure has been reported by Maisano and colleagues.17

Patient Selection

Patients were selected if they met basic criteria for intervention from the European Society of Cardiology Task Force recommendation on the management of valvular heart disease.1 Indication for MitraClip therapy was given according to local institutional practice in consideration of current CE mark–approved labeling. Eligible patients included those with symptomatic moderate-to-severe (3+) or severe (4+) MR. Transsthoracic and transesophageal echocardiograms studies were evaluated at baseline to assess patient eligibility.

All patients underwent a multimodality decision-making process by a dedicated multidisciplinary Heart Team, including evaluation of surgical risk by logistic European System for Cardiac Operative Risk Evaluation (EURO) (http://www.euroscore.org/) and Society of Thoracic Surgeons (STS) score (http://riskcalc.sts.org/STSWebRiskCalc273/), as well as adjunctive risk evaluation, such as the presence of advanced liver cirrhosis and severe neurologic impairment. Frailty and biological status were evaluated by the institutional Heart Team after collegial discussion, according to the so-called eyeball test. Quality of life of all the patients was evaluated by the Minnesota Living with Heart Failure Questionnaire (MLHFQ) and the 36-Item Short-Form Health Survey (SF-36); the 6-minute walk test (6MWT) was used to evaluate functional capacity.

Follow-up

All patients were followed up after discharge in a dedicated outpatient clinic with physical examination, electrocardiogram, transthoracic echocardiogram, and arythmology consultation whenever indicated. Follow-up visits were performed at 1 month, 6 months, and then yearly.

Statistical Analysis

Statistical analysis was conducted using JMP 11.0 software (SAS Institute Inc, Cary, NC). Continuous variables are presented as mean ± standard deviation or as median (interquartile range [IQR], Q1-Q3), and categoric variables are expressed as percentages. Univariable comparisons were performed with Student unpaired or paired t test for continuous normally distributed data, which were tested by the Shapiro–Wilk normality test. The Mann–Whitney rank-sum test was used for comparisons of nonparametric continuous data, and the chi-square test was used for categoric data. Survival and freedom from 3+ or greater MR were presented using the Kaplan–Meier method; comparisons were performed with the log-rank test. All reported P values are 2-sided.

RESULTS

Patient Characteristics

The study population consisted of 48 high-risk consecutive patients with severe or moderate to severe DMR who underwent MitraClip implantation between October 2008 and July 2013 in San Raffaele University Hospital, Milan. During the same period, 2370 patients underwent surgical mitral repair (with or without associated procedure), and 116 patients underwent MitraClip implantation for functional MR.

The mean age of the study population was 78.5 ± 10.8 years; 56.6% of the patients were aged 80 years or more. The mean logistic euroSCORE at baseline was 15.7 ± 11.2; the mean STS score was 12% ± 10% (range, 2%-36%; IQR, 4-18); 40% and 45.5% of patients had a baseline logistic euroSCORE 20% or greater and STS score 10% or greater, respectively. Patients presented multiple comorbidities. The baseline characteristics of all the patients are summarized in Table 1 (including data from ACCESS-EUROPE (ACCESS-EU) phase I DMR cohort for comparison).13 Stratification into patients aged less than 80 years and patients aged 80 years or more revealed important demographic differences (mean logistic euroSCORE...
The majority of the patients had severe symptoms of heart failure at baseline, with 60.5% in New York Heart Association (NYHA) functional class III and 10.5% in class IV. Quality of life questionnaire revealed an important impairment in perceived quality of life in all patients (MLHFQ was 33.8 ± 7.9; SF-36 physical domain was 38.6 ± 8.7; SF-36 mental domain was 42.5 ± 8.7). A tendency toward worst perceived quality of life was observed in patients aged 80 years or more (MLHFQ 33 ± 14 vs 36 ± 8; P = .3; SF-36 physical domain 40.6 ± 6 vs 44.2 ± 8; P = .06; SF-36 mental domain 42.7 ± 9 vs 42.8 ± 8; P = .4). Patients aged more than 80 years had the worst performance on the 6MWT (262.3 ± 110.4 minutes vs 180.1 ± 64.7 minutes; P = .004).

Procedural and In-Hospital Outcomes

The device was successfully implanted in 47 of 48 patients (98%); 1 patient was converted to conventional surgical MV replacement because of clip entanglement in the subvalvular apparatus in the commissural region, with the impossibility to retrieve the device. One clip was implanted in 16 patients (33.3%), 2 clips were implanted in 29 patients (60.4%), and 3 clips were implanted in 2 patients (4.1%). The median procedural time (defined as the time from start of the transseptal procedure until the removal of the Steerable Guide Catheter) was 94 minutes (IQR, 69-130 minutes; 6 minutes less compared with ACCESS-EU DMR).13

Safety outcomes at 30 days are shown in Table 3; 30-day mortality was 2% (1/48 patients died of septic shock and multiorgan failure after conversion to open mitral surgery). There was no incidence of acute myocardial infarction, stroke, major vascular complication, or cardiac tamponade at 30 days. Blood transfusion was required in 2 patients (4%); severe acute renal failure occurred in 1 patient.

</table>
The median stay in the intensive care unit was 22 hours (IQR, 18-24 hours); the stay in the intensive care unit was less than 1 day in 75% of patients (36/48). Patients were discharged from the hospital in an average of 4.5/C6 2.4 days (4.3/C6 3 days and 4.7/C6 1.5 days for patients aged <80 years and ≥80 years, respectively; P = .7), with a median of 4 days after the MitraClip procedure. A minority of the patients were transferred to a cardiopulmonary rehabilitation facility (2 patients aged <80 years and 2 patients aged ≥80 years; P = .8): 91.5% of hospital survivors (43/47 patients) were discharged directly home.

Predictive echocardiography showed an MR reduction to grade 2+ or less in 43 of 47 patients (91.5%); 29 of 47 patients (61.7%) achieved an MR reduction to grade 1+ or less. No differences in MR grade reduction were observed according to age group (Figure 1). No cases of mitral stenosis were observed: Postprocedural median MV area was 3 cm² (IQR, 2.7-3.1 cm²), and predischARGE systolic pulmonary artery pressure was 37.8 ± 10 mm Hg (P = .03 compared with baseline).

Follow-up

The median follow-up was 16 months (IQR, 2-23 months). Overall actuarial survival was 89% ± 5.2% and 70.2% ± 9% at 1 and 2 years, respectively, for the entire study population; no differences were observed between patients aged less than 80 years and patients aged 80 years or more (82% ± 9% and 95% ± 4.4% at 1 year, respectively; P = .7) (Figure 2). Causes of death were classified as cardiac in 33% of the cases. After discharge, 1 patient (2%) underwent mitral surgery 2 years after the procedure; 1 patient (2%) repeated the MitraClip procedure 1 month after the index procedure.

Actuarial freedom from MR 3+ or greater was 80% ± 7% at 1 year and 76.6% ± 7% at 2 years (Figure 3). There were no statistically significant differences in patients aged less than 80 years compared with patients aged 80 years or more (86.5% ± 8% and 75% ± 9%, respectively; P = .5). At 1 year, 93% of survivors were in NYHA class I or II (100% of patients aged <80 years and 88% of patients aged ≥80 years; P = .4) (Figure 4).

A significant improvement was documented with all the quality of life assessments: MLHFQ was 18.1 ± 10, SF-36 physical domain was 44.3 ± 7, and SF-36 mental domain was 49 ± 8.3 (P < .0001, P = .005, and P = .01, respectively, compared with preoperative values). A significant improvement in 6MWT performance was observed (262 ± 91 minutes; mean improvement, 48 minutes;
P = .005). Significant improvements in perceived quality of life and performance of 6MWT were observed in both patients group (Figure 5, A and B).

DISCUSSION

Surgical MV repair is the treatment of choice for patients with severe DMR.20,21 Therefore, modern MV surgery is the benchmark for any new technique today, including MitraClip therapy. However, MR is a frequent condition in elderly persons (especially degenerative cause).9,22 Advanced age is one of the main risk factors of mortality and morbidity after cardiac surgery (~78% of the major complications after cardiac surgery and deaths occurred in elderly patients).23 Although favorable outcomes are reported even in elderly patients after isolated mitral repair,3 operative mortality and morbidity are high in elderly patients in the presence of co-pathologies and associated surgical procedures.22

Badhwar and colleagues24 recently reported the outcomes after MV repair in 14,604 patients aged more than 65 years. In patients aged more than 80 years with advanced heart failure symptoms (NYHA class III-IV), operative mortality was 5.3% and 5-year survival was 68%. The 5-year rates of recurrence of heart failure, major bleeding, and stroke were 28.8%, 12.3%, and 11.7%, respectively.

Seeburger and colleagues25 reported the single-center experience with 2053 elderly (aged ≥70 years) patients who underwent MV surgical procedures with or without associated procedures. Seventy-seven patients (3.1%) died within 30 days after the operation. Cerebrovascular accidents occurred in 4.2% of patients, and the incidence of acute renal failure was 16.7%. Concomitant coronary artery bypass grafting was a significant risk factor for increased early mortality. Five-year survival for patients aged more than 80 years was 47.9%, and associated comorbidities were associated with an increased risk of late death.

Chikwe and colleagues26 reported the results of a consecutive series of 322 octogenarians operated over a period of 10 years. Approximately half of the patients underwent MV surgery combined with coronary artery bypass grafting. The surgical risk was apparently acceptable only in patients treated with an isolated elective repair, with a mortality of approximately 5% at 30 days. However, mortality at 3 months was approximately 13%, indicating that octogenarians are not likely to recover easily from the trauma of open surgery.

Currently, up to 50% of the patients with severe MR are not referred for surgery because of high predicted surgical risk or advanced age.8 According to the European Society of Cardiology 2012 Guidelines,7 percutaneous edge-to-edge procedure may be considered in patients with symptomatic severe DMR who fulfill the echocardiographic criteria of eligibility, are judged inoperable or at high surgical risk by a heart team, and have a life expectancy greater than 1 year (class IIb, level of evidence C).

Data from the Endovascular Valve Edge-to-Edge Repair of Mitral Regurgitation Study (EVEREST) trials and from registries in Europe and the United States showed that the MitraClip procedure has a procedural success rate (postprocedural MR ≤2+) of approximately 75% and is relatively safe and generally well tolerated, even by patients in poor clinical condition.10-18 Patients currently treated in the real world with MitraClip therapy for DMR are different from those enrolled in the EVEREST II randomized trial, which included surgical low-risk candidates. The High Risk Registry Study, an arm of the EVEREST II trial, enrolled symptomatic patients with moderate to severe or severe MR for whom surgical risk for perioperative mortality rate was estimated to be greater than 12% with STS score. In this series, 88.5% of the patients had 5 or more associated co-pathologies and 83% of the patients were aged more than 75 years.17 A degenerative cause was present in 62 patients. At 30 days, 4 of 62 patients (6.5%) with DMR who were treated with MitraClip died.
The results of the DMR cohort of the ACCESS-EU Phase I study showed satisfactory clinical outcomes in selected high-risk patients: A total of 117 patients (mean age, 75.6 ± 12 years; mean logistic euroSCORE, 15.5% ± 13.3%) with DMR underwent the MitraClip procedure. However, a 30-day mortality of 6.0% was reported. In a subgroup of patients with particularly high risk (mean logistic euroSCORE 33% ± 11%), observed mortality was 9.1%. Likewise, Lim and colleagues reported a 6.3% 30-day mortality in 141 high-risk patients with DMR (mean age, 82 years).

The major finding of the present study concerns the high level of safety of MitraClip therapy in high-risk and elderly patients with DMR if appropriate patient selection is performed. In our experience, 30-day mortality was remarkably low (2% overall; 3% in patients aged >80 years). Although patients treated in San Raffaele University Hospital experience were older compared with those in the ACCESS-EU DMR, they had a similar baseline risk profile (logistic euroSCORE, 15.7 ± 12.2). The relatively higher 30-day mortality reported in the registries may reflect the fact that they are real-world registries, in which many procedures, at least at the beginning of the enrollment, were performed in very sick patients as compassionate and probably futile treatment. The low mortality and extremely low morbidity reported in our experience show the importance of careful patient selection to identify those who could benefit from the procedure and to reduce procedural risk.

![Graphs](https://example.com/graphs.png)

**FIGURE 5.** A, Results of MLHFQ in patients aged less than 80 years and patients aged 80 years or more. B, Results of 6MWT in patients aged less than 80 years and patients aged 80 years or more. MLHFQ, Minnesota Living with Heart Failure Questionnaire; 6MWT, 6-minute walk test.
It is important to point out that patient selection is fundamental to obtain successful procedural results. In our experience, we observed a procedural success of 98%, which is satisfactory, especially in degenerative cause, and favorably compares with other large real-world MitraClip series of patients with DMR (94% in ACCESS-EU DMR, 13 ~80% reported by Rudolph and colleagues14 in patients with DMR).

At follow-up, we observed an actuarial survival of 89% ± 5.2% and 70.2% ± 9% at 1 and 2 years, respectively, without differences between patients aged less than 80 years and patients aged 80 years or more, which favorably compares with other MitraClip series (1-year mortality ranging from 6% to 24%) and with the previously mentioned surgical reports.15-18

In regard to echocardiographic outcome, our experience showed an acute reduction of MR to grade 2+ or less in 91.5%, and in 61.7% an MR reduction to grade 1 or less was achieved. These results are consistent with those reported in the ACCESS DMR registry (reduction of MR to grade ≤2+ in 88.7%) and favorably compared with the EVEREST II trial (77%).10,13 Freedom from MR 3+ or greater was 80% ± 7% and 76.6% ± 7% at 1 and 2 years, respectively. If compared with reparative mitral surgery, these results are inferior, confirming that surgery is so far the gold standard therapy for DMR. However, it should be considered that the patients included in the present study, like the majority of the patients currently treated with MitraClip, are high-risk surgical candidates or inoperable patients. Although estimated surgical risk was high, meaningful clinical improvements were documented. In fact, except for intraoperative and early postoperative risks, it would seem equally or even more important, especially in elderly patients, integrated evaluation of the quality of life and functional status, to judge whether a certain procedure could lead to the expected functional improvement. In a retrospective study including 225 patients aged more than 70 years who underwent mitral surgery for severe DMR, Maisano and colleagues57 demonstrated that quality of life after surgery is suboptimal in more than half of the patients, even if the patient survives after the operation.

Important clinical benefits were documented at 1 year even in patients aged more than 80 years, in terms of NYHA class, quality of life, and functional status tested by walk test improvements. In our experience, MLHFQ scores, SF-36 scores, and 6MWT performance improved significantly at 12 months compared with baseline (P = .03 and P < .0001, respectively). Significant improvements were observed in patients aged more than 80 years. This is consistent with the ACCESS-EU DMR results at 1 year and with other reports in different clinical settings.10,12,17,28

Study Limitations
This study was an observational, retrospective, single-center study; therefore, the sample size is too small to make strong conclusions. Moreover, the results include an initial learning curve.

CONCLUSIONS
The results of this single-center experience confirm that MitraClip therapy is a valuable alternative to surgery in high-risk and elderly patients with DMR. Clinical benefits are evident at 1 year and also obtained in octogenarians. Although patients treated in current practice are high risk, the procedure remains safe and effective in selected patients. Durability of MR reduction and clinical benefit warrant further monitoring of patients after MitraClip implantation during long-term follow-up.

Percutaneous edge-to-edge repair for degenerative mitral regurgitation: A journey to the edge of the bell-shaped curve

Patrick M. McCarthy, MD

The report in this issue of the Journal by Taramasso and colleagues is a welcome addition, as most reports of MitraClip (Abbott Vascular, Santa Clara, Calif) outcomes have been in the cardiology literature. Taramasso and colleagues report excellent outcomes in a high-risk surgical population (78.5 ± 10 years; 71% New York Heart Association functional class III or IV). Mean Society of Thoracic Surgeons [STS] score 12% ± 10%) with severe degenerative mitral regurgitation (DMR). Their results mirror the US MitraClip experience presented to the Food and Drug Administration panel with a low procedural risk (2% in-hospital mortality), low morbidity, no clip embolization, a very high procedural “success” rate (98%), and short stay relative to conventional surgery. DMR is frequently seen with an anatomically difficult lesion to treat with the MitraClip; however, there was a reasonable reduction in mitral regurgitation to grade II or less in 91.5% of patients. The 1-year survival (89% ± 5.2%) was 91.5%. New York Heart Association functional class (93% I or II), and 6-minute walk (mean improvement of 48 meters) were favorable. Initial trials in the United States included low- and medium-risk patients, the type of patients in the middle of the bell-shaped curve of patients treated with surgery, and reflected a strategy (and hubris) to compete directly with conventional heart surgery. These trials, principally the Endovascular Valve Edge-to-Edge Repair High Risk Study (EVEREST) and the continued access protocol, took a long time to execute as the tactics evolved and the target patient population shifted to the sickest patients on...
