The kissing stents technique for a patient with chronic type B aortic dissection

Akihiro Yoshitake, MD, PhD, Takashi Hachiya, MD, PhD, Kanako Hayashi, MD, and Hideyuki Shimizu, MD, PhD, Tokyo, Japan

Thoracic endovascular aortic repair has recently become widespread for patients with thoracic aneurysm. For patients with chronic type B aortic dissection, however, in whom the visceral arteries originate from a false lumen, blood flow from the false lumen is not always occluded, and there is concern that aneurysmal enlargement may occur in the false lumen through reentry.1 We describe here the “kissing stent” technique, in which 2 stent-graft main bodies are aligned in a parallel manner and the distal landing of one stent is placed into the true lumen with another stent graft placed into the false lumen.

CLINICAL SUMMARY

A 67-year-old man with an asymptomatic 72-mm saccular descending aortic aneurysm had a history of acute aortic dissection 12 years earlier and had undergone Y-grafting to the abdominal aortic aneurysm, proximal descending aortic replacement, and total arch replacement. He also had chronic obstructive pulmonary disease, coronary artery disease, and cerebral infarction and was therefore considered at high risk if undergoing open surgery. The aneurysm was located in the middle portion of the descending aorta. The distal descending aorta and thoracoabdominal aorta were double-barreled, and neither lumen was enlarged. The superior mesenteric and right renal arteries originated from the true lumen, and the celiac and left renal arteries originated from the false lumen.

An endovascular stent-graft operation was performed. The stent-graft main body (Gore TAG Thoracic Endoprosthesis; W.L. Gore and Associates, Flagstaff, Ariz) was delivered through the true lumen and placed into a prosthetic graft in the proximal descending aorta. The main body of another stent graft of the same size was inserted through the false lumen, with the upper end placed at almost the same level as the first stent graft. The grafts were deployed simultaneously at the same height. To secure the length of the proximal landing, the proximal extension cuff (Zenith Tx2 Thoracic Endoprosthesis; Cook Medical, Bloomington, Ind) was delivered into one side and the other cuff into the other side (Figure 1). Simultaneous touch-up

was performed with a Coda Balloon Catheter (Cook Medical) in a kissing manner. Intraoperative angiography and postoperative computed tomographic angiography with delayed venous and arterial phases demonstrated good flow in both lumens, no endoleaks, and good stent-graft positioning (Video 1). The patient recovered fully without serious perioperative complications. Six months postoperatively, computed tomographic angiography showed aneurysm shrinkage and no endoleak (Figure 2). The patient’s course remained uneventful at 11 months after surgery.

**DISCUSSION**

Endovascular treatment for acute type B aortic dissection has become widespread, with acceptable results. The International Registry of Acute Aortic Dissection reports that the 5-year mortality among patients treated with thoracic endovascular aortic repair was superior to that among medically treated patients (15.5% vs 29.0%; $P = .018$).²

The use of thoracic endovascular aortic repair in patients with chronic type B aortic dissection, however, remains controversial. Relative to patients with acute aortic...
dissection, patients with chronic dissection display less consistent aortic remodeling (thoracic false-lumen thrombosis in 31%-91% among patients with chronic dissection vs 80%-90% among patients with acute dissection). Stent-graft coverage of the primary entry tear is often insufficient, leading to aneurysm formation in the distal aorta. In addition, some techniques have been shown to occlude the false lumen and promote thrombosis and false-lumen remodeling.

The technique described here has some merit. The stent graft implanted into the false lumen completely blocked blood flow to the aneurysm and preserved blood flow to the celiac and renal arteries. In this case, neither the true nor the false lumen thrombosed, and neither lumen was perfused by the patent intercostal arteries, suggesting that this technique could be performed successfully. In our report, the false lumen served as the distal landing zone of one stent graft. After our patient’s treatment for aortic dissection 12 years previously, the diameters of the distal descending aorta and thoracoabdominal aorta were nearly normal and did not change during follow-up. They thus appeared to have sufficient wall strength for stent-graft implantation.

This novel kissing stent technique was used effectively for a chronic aortic dissection aneurysm. It excluded the aneurysm completely and maintained blood flow to the visceral arteries. This technique may be an alternative for patients considered to be at high risk if undergoing open surgery.

EDITORIAL COMMENTARY

**Innovation is mandatory in chronic type B aortic dissection**

Rune Haaverstad, MD, PhD, and Guttorm L. Jenssen, MD

Chronic type B aortic dissection (cTBAD), either primary or secondary after open surgery for acute type A aortic dissection, remains a threat for the patient and a major medical challenge. The cTBADs are heterogeneous with regard to patient-related risk factors, interval since onset, morphology, false-lumen status, site, and numbers of entries and reentries, as well as varying origins of the spinal and visceral arteries. In the long run, rupture of a false lumen aneurysm causes most of the dissection-related mortality. Traditionally, cTBAD has been treated with open surgery, but because this carries a high risk in patients...
