Repair of type III common arterial trunk with modified Barbero-Marcial technique

Juan M. Aguilar, MD,a Enrique Garcia, MD, PhD,a Francesco G. Arlati, MD,b and Juan V. Comas, MD, PhD,a Madrid Spain, and Milan, Italy

Right ventricular outflow tract (RVOT) reconstruction is a controversial issue in common arterial trunk repair. Usually, this procedure is accomplished by interposition of a conduit, valve or nonvalved, between the right ventricle and the pulmonary arteries. Conduit degeneration is fast in patients aged <12 months, especially in those implanted in heterotopic position during the neonatal period, as in truncus arteriosus repair.1

In 1990, Barbero-Marcial and colleagues2 described a technique for RVOT reconstruction in Collet-Edwards3 type II common arterial trunk without the interposition of a conduit. This technique involves a direct anastomosis between the pulmonary trunk and the infundibular ventriculotomy.

In this article, we describe a modification of the Barbero-Marcial technique to treat type III truncus arteriosus, which comprises the interposition of the left atrial appendage between the right ventricle and the pulmonary trunk. We present intraoperative pictures of a patient with a prenatal diagnosis of type III common arterial trunk who underwent complete repair with a modified Barbero-Marcial technique at 3 weeks of age (Figures 1 and 2).

Early postoperative recovery was complicated by left ventricle dysfunction that required ECMO, probably because of inadequate myocardial protection caused by left main trunk distortion after pulmonary artery clamping. On postoperative day 6, the patient was weaned from ECMO support. Subsequently, he developed mainly diastolic right ventricle dysfunction.

FIGURE 1. A, Collet-Edwards type III common arterial trunk showing ligation of a small arterial duct and left pulmonary artery isolation (red vessel loop). B, Closure of the ventricular septal defect with a heterologous pericardial patch, and reconstruction of the posterior surface of the new right ventricular outflow tract with an anastomosis between the left atrial appendage and the posterior rim of the ventriculotomy proximally, and the posterior rim of the pulmonary trunk distally.
dysfunction. After complete recovery with medical therapy he was discharged in good general condition.

Patients with common arterial trunk (CAT) who have undergone neonatal biventricular repair are inevitably burdened with multiple catheter and surgical reinterventions on their right ventricle-to-pulmonary artery (PA) conduit and branch PAs. The lack of growth potential in a small right ventricle–PA conduit implanted in the neonatal period mandates early exchange surgery, and...
