Biventricular root replacement for transcatheter pulmonary valve endocarditis after Ross operation: Double the trouble

T. K. Susheel Kumar, MD, Kaitlin Balduf, MD, Umar Boston, MD, and Christopher Knott-Craig, MD
Memphis, Tenn

Use of percutaneous pulmonary valve replacement (PPVR) has steadily increased during the last decade, even though increased risk of endocarditis continues to be a concern. The close proximity of the right ventricle–pulmonary artery (RV-PA) conduit to the dilated neoaorta after the Ross operation poses unique challenges for PPVR. Stent fractures, accelerated progression of neoaortic regurgitation, aortopulmonary fistula, and coronary compression are well-documented complications of PPRV after the Ross operation. We draw attention to the dangers of Melody valve (Medtronic Inc, Minneapolis, Minn) endocarditis in the setting of Ross operation and to the surgical challenges it poses.

CASE DESCRIPTION

A 22-year-old syndromic man was admitted to the hospital for complaints of increasing fatigue, weight loss, intermittent fevers, and increased seizure activity of 6 months’ duration. He had undergone 5 previous sternotomies and cardiac operations, including a Ross operation at 4 years of age and bioprosthetic aortic valve replacement at 16 years. Four years later, he had stenosis of the RV-PA homograft conduit, which was managed by prestenting of the conduit, and PPVR was managed with a 22-mm Melody valve. Two years later, he had obstruction and culture-positive Streptococcus viridans endocarditis of the Melody valve. At this time the aortic root was moderately dilated, and the aortic bioprosthesis was functioning normally (Figure 1). Despite intravenous antibiotics, the endocarditis progressed, and 6 weeks later there was echocardiographic evidence of new severe aortic bioprosthesis obstruction (gradient 110 mm Hg), and severe Melody valve obstruction (gradient 115 mm Hg; Figure 2).

He was taken to the operating room for emergency surgical replacement of both aortic valve and RV-PA conduit (Video 1). Dense pericardial adhesions were encountered from severe inflammation around the infected Melody valve and RV-PA conduit. The metal stent in the main pulmonary artery had eroded into the wall of the aortic root, thereby precluding placement of the aortic crossclamp until after the pulmonary root had been excised on cardiopulmonary bypass. The aortic crossclamp was then applied and the heart arrested with Custodiol cardioplegic solution (Custodiol HTK; Köhler Chemie GmbH, Bensheim, Germany). The aortic bioprosthesis was found to be infected with large vegetations, and the stent was found eroding into the wall of the aortic root. The valve was excised, and the aortic root was resected completely. Aortic root replacement was achieved with a 23-mm cryopreserved aortic homograft.

Echocardiogram showing spread of endocarditis from pulmonary to aortic valve (red line).

Central Message
Endocarditis of percutaneous pulmonary valve in setting of a previous Ross operation poses surgical challenges. It may be necessary to excise the pulmonary valve before aortic crossclamping.

CONGENITAL: AORTIC VALVE: CASE REPORT
The pulmonary root was replaced with a 23-mm pulmonary homograft during rewarming. The total cardiopulmonary bypass duration was 258 minutes, and the aortic crossclamp time was 107 minutes. The patient was weaned from cardiopulmonary bypass without difficulty and recovered completely without significant morbidity. The antibiotics were continued for duration of 6 weeks. Echocardiography performed more than a year after bilateral outflow tract replacement demonstrated nicely functioning aortic and pulmonary valves with preserved ventricular function and without any signs of endocarditis.

DISCUSSION

The Ross operation restores a functional aortic valve, but the pulmonary artery conduit may need replacement down the road. The PPVR has been used by some to extend the longevity of the surgically placed RV-PA conduits. Melody PPVR after the Ross operation, however, sets up unique challenges. Increased risk of stent fractures is well documented. Accelerated progression of the neoaortic insufficiency caused by the rigid metal stent has also been reported. Aortopulmonary fistula and coronary compression are other concerns. In addition, reoperation on the Melody valve encased in the metal cage juxtaposed to the aortic autograft is a particularly challenging problem, as evidenced in this report.

Gillespie and colleagues described a large series of 56 patients who underwent Melody PPRV for conduit dysfunction after the Ross procedure. Of these 56 patients, 60% had metal or covered stents before Melody valve placement. The PPVR with Melody valve was associated with satisfactory early and midterm outcomes. Endocarditis occurred in 10% of the patients during a median follow-up period of 4 years. Three patients required surgical explantation, although details were not mentioned.

The unique combination of aortic root dilation and orthotopic position of the graft brings the aortic wall and homograft into very close proximity. Prestenting of conduit with a rigid stent further accentuates this, making spread of infection to the contiguous structures very easy although in our patient the aortic bioprosthesis may have enhanced the process. Surgical management can become extremely challenging in such circumstances. A preprocedural transeophageal echocardiogram must be performed to rule out any septal defects. Aortic root vent affords protection against air embolism. During the operation, it may be difficult if not impossible to dissect the aortopulmonary plane to make room for the aortic crossclamp. It may be necessary to excise the stent and Melody valve on a beating heart before crossclamp application. Elective ventricular fibrillation may be necessary in the presence of septal defects. The predisposition of the Melody valve toward endocarditis, reluctance to refer these patients for early reoperative surgery, and initial preference to treat prosthetic valve endocarditis medically can prove disastrous and make for extremely challenging surgery. Earlier intervention may be warranted in these situations.
